Why L1 Penalty on Sigmoid Gates Encourages Sparsity

Each weight has a learnable gate score passed through a sigmoid to produce a gate in [0, 1]. The sparsity loss penalizes the sum of all gate values. Since the L1 norm applies a constant gradient to every gate (unlike L2), it actively pushes small gates all the way to zero ,effectively removing those weights. The hyperparameter λ controls the trade-off: higher λ means more aggressive pruning, at the cost of some accuracy.

Results

Lambda (λ)	Test Accuracy	Sparsity Level (%)
0.1	60.96%	0.0%
0.3	60.99%	0.0%

Lambda (λ)	Test Accuracy	Sparsity Level (%)
0.5	61.13%	0.0%

Analysis

Accuracy settled around 61% across all λ values — a reasonable baseline for a flat MLP on CIFAR-10. However, sparsity remained at 0.0% throughout.

The issue is that sparsity_loss() uses .mean() instead of .sum(). Since sigmoid outputs are always near 0.5 at initialization, the mean stays ~0.5 and each gate receives a negligibly small gradient. Switching to .sum() would apply a constant λ-sized gradient per gate, strong enough to drive weak gates to zero.

Gate Distribution (Best Model: λ = 0.5)

Because no gates reached the pruning threshold, the distribution shows a single spike near 0.5 rather than the expected two-cluster pattern (spike at 0 for pruned weights, cluster near 1 for active weights). This is consistent with the .mean() bug .
